Opinion
about the results of testing the fuel catalyzer

The fuel catalyzer is designed to reduce the toxicity of exhaust gases and the specific fuel consumption of gasoline and diesel engines.

The chamber-cassette-type device, installed in the system of the fuel pipe of the machine, contains filters-activators of fine cleaning, chemical active elements, granular active elements.

The development has a novelty of a global scale and significant results in the field of combustion efficiency of liquid fuels.

The indirect results of the use of the catalyzer are the increase in the engine's life, the increase of the uniformity of engine operation in the cylinders.

In the conditions of rising prices for hydrocarbon fuels, toughening environmental requirements, equipping vehicles with fuel catalyzers is an urgent and effective way to resolve these problems.

Carried out tests on various types of transport show the decrease in the specific fuel consumption by 12-20%, and emissions of toxic gases by 5-10 times.
